

Since part 1, the database now filters out all “/” in the description as well as null values for the bidderID. The database was also moved from SQLite to MySQL using .dump which then required both the description and location in the tblItems table to be changed from varchar to longtext as well as take out the extra “insert into” that sqlite makes in the .SQL file (these were done by hand). The only other change is there is a new table “credentials” which is used to verify the user’s username and password.

The part 2 creating triggers, was done in the php file instead of on the database itself.
